## Problem 1

Let F be a field of prime characteristic p. Suppose  $E = F(\alpha)$  such that  $\alpha \notin F$  but  $\alpha^p - \alpha \in F$ .

- 1. Find [E : F].
- 2. Prove that E/F is a Galois extension.
- 3. Find the Galois group Gal(E/F).

**Hint:** Note that 
$$(x + 1)^p - (x + 1) = x^p - x$$
. <sup>a</sup>

## Proof.

1. This is the hardest part: Let's denote  $b = \alpha^p - \alpha \in F$ . Consider the polynomial

$$f(x) = x^p - x - b.$$

Clearly from the hint, we can see that  $\alpha+k, k=0,1,\ldots,p-1$  are roots of f(x). They are all distinct. Thus

$$f(x) = \prod_{k=0}^{p-1} (x - \alpha - k)$$

If this polynomial is reducible over F, then there exists n < p such that

$$g(x) = \prod_{i=0}^{n-1} (x - \alpha - k_i) \in F[x]$$

But this implies that the coefficient of  $x^{n-1}$  in g(x) is

$$n\alpha + k_0 + k_1 + \ldots + k_{n-1} \in F$$

which implies  $\alpha \in F$ , a contradiction. Thus f(x) is irreducible over F.

- 2. This follows immediate from part 1 that f is irreducible and has p distinct roots. Thus the splitting field of f is E and  $E = F(\alpha)$  is separable as  $\alpha$  is separable over F. Thus E/F is a Galois extension.
- 3. The Galois group is a group of order p, thus it is isomorphism to  $\mathbb{Z}/p\mathbb{Z}$ .

## Problem 2

Let  $\zeta:=e^{2\pi i/7}$  be a primitive 7th root of unity. Let  $K=\mathbb{Q}(\zeta)$ .

- 1. Prove that there exists an element  $\alpha \in K$  such that  $[\mathbb{Q}(\alpha) : \mathbb{Q}] = 2$ .
- 2. Express  $\alpha$  in terms of  $\zeta$ .

*Proof.* We will prove two items at once. Consider the element given by

$$\alpha = \zeta + \zeta^2 + \zeta^4$$

<sup>&</sup>lt;sup>a</sup>This is the Artin-Schreier polynomial.

Then it can be seen that the map  $\sigma$  such that  $\sigma$  such that  $\sigma(\zeta) = \zeta^3$  generates the Galois group of the cyclotomic field. This implies the desired field extension will correspond to the fixed field of the subgroup generated by  $\sigma^2$ . We can see that the  $\alpha$  defined as above is fixed by  $\theta = \sigma^2$ . Indeed

$$\theta(\alpha) = \sigma^2(\zeta + \zeta^2 + \zeta^4) = \zeta^9 + \zeta^4 + \zeta^{36} = \zeta^2 + \zeta^4 + \zeta = \alpha$$

Clearly  $\alpha \notin \mathbb{Q}$ , since  $\zeta$  has degree 6 over  $\mathbb{Q}$ . Moreover,  $\alpha$  can't have degree 3 over  $\mathbb{Q}$ , otherwise it is inside the intersection of two intermediate fields of degree 2 and 3, thus is rational. Hence we can conclude that this is the desired element.

**Remark:** A Sage code for this problem is given below.

```
k = CyclotomicField(7); k
zeta=k.gen(); a = zeta+zeta^2+zeta^4
a.minpoly()
```
